

THE EFFECT OF NITROGEN OXIDE
EMISSIONS FROM AUTOMOBILE
TRAFFIC ON THE CONCENTRATION
OF TROPOSPHERIC OZONE IN THE
GREAT SMOKY MOUNTAINS
NATIONAL PARK

STUDENT:

James W. Herndon III (New Mexico State University)

MENTORS:

Dr. Joshua S. Fu (University of Tennessee),

Dr. Rick D. Saylor (National Oceanographic and
Atmospheric Administration, University of Tennessee)

A lush, green forest scene featuring a narrow dirt path that winds through the trees. The ground is heavily covered in vibrant green moss, particularly on large, rounded rocks and tree stumps. The trees are tall and thin, with a mix of deciduous and coniferous species. The lighting is soft and dappled, creating a serene and natural atmosphere. The text 'THE PROJECT' is overlaid in the center of the image in a clean, white, sans-serif font.

THE PROJECT

GREAT SMOKY MOUNTAINS NATIONAL PARK

- ◉ Most visited national park in the United States of America (~9,000,000 visitors/year).
- ◉ The majority of park visitors drive through the park to various hiking, camping or sightseeing destinations, resulting in substantial emissions of nitrogen oxides (NO_x) from vehicle exhaust. NO_x, when combined with hydrocarbon emissions from natural vegetation can lead to ozone, a primary component of photochemical smog, which can be damaging to plants, animals and humans.
- ◉ The primary goal of our project is to initially assess how NO_x emissions from visitor traffic in the park may affect concentrations of ground-level (tropospheric) ozone.

A photograph of a lush forest floor. The ground is covered in vibrant green moss, particularly on large, rounded rocks. A narrow dirt path winds through the scene, leading towards the background. Tall, thin trees with green foliage form a dense canopy overhead. The lighting is soft and natural, highlighting the textures of the moss and the forest environment.

THE ATMOSPHERIC CHEMISTRY AND CANOPY EXCHANGE SIMULATION SYSTEM (ACCESS)

ACCESS

- It is a one-dimensional column model that utilizes a current state-of-the-science, near explicit atmospheric chemistry mechanism to simulate tropospheric ozone (and other compounds) from the ground level to the top of the planetary boundary layer (PBL) (~2 km above ground level).

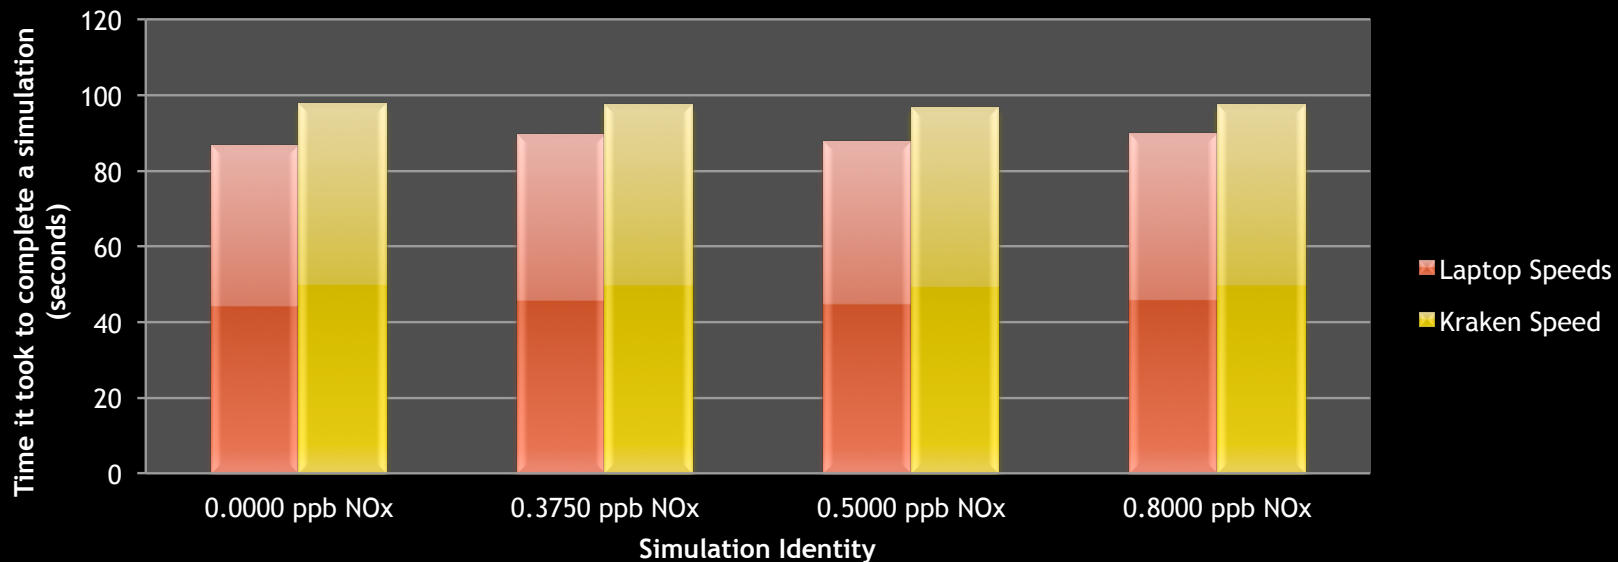

A photograph of a dense forest. The ground is covered in vibrant green moss, particularly on large, rounded rocks. A narrow dirt path winds through the trees, leading towards the background. The trees are tall and thin, with some evergreen foliage visible. The overall atmosphere is serene and natural.

RESULTS

INITIAL TESTS

- Initially our plans were this:
 - Assess how ACCESS runs on an HPC platform and attempt to optimize it.
 - The graph below shows the results from our initial tests on Kraken versus my personal laptop.

Simulation Speed

A SLIGHT CHANGE OF PLAN...

- We decided not to use Kraken because it has strict time constraints on simulations (i.e., 24 hrs maximum for a simulation for a regular user). This was not acceptable, as we needed to run the full ACCESS program soon and did not have time to parallelize the code.
 - The serial code of ACCESS itself takes around 30 CPU hours to run; this would not be possible to do on Kraken.
- Solution: Abandon the thought of using Kraken, and use Star1 (a computer at University of Tennessee), which has no time constraints.

SIMULATION RESULTS FROM STAR1

- We did two simulations on Star1:
 - 1st simulation: Neutral Atmospheric Conditions
 - With this simulation, we did not get much vertical transport, which meant that we did not get much NO_x transported above the canopy, for possible reactions. Because of this, we decided to do a second simulation.
 - 2nd simulation: Unstable Atmospheric Conditions
 - More enlightening results came from this simulation. There is more transportation of NO_x above the canopy. This allowed for a more accurate representation of the impact of NO_x on the photochemistry above the canopy. These are the results used in the upcoming slides.

A photograph of a dense forest. The ground is covered in vibrant green moss, particularly on large, rounded rocks. A narrow dirt path winds through the forest, leading towards the background. Tall, thin trees with green foliage surround the path. The lighting is soft, suggesting a shaded forest environment.

SPECIES GRAPHS

STRUCTURE OF SEVERAL OF THE SPECIES YOU WILL BE SEEING GRAPHS OF

○ From top-left clockwise:

- Nitrogen dioxide (NO_2)
- Nitric oxide (NO)
- Nitrogen oxides (NO_x)
- Methacryloyl peroxy nitrate (MPAN)
- Peroxyacetyl Nitrate (PAN)
- Ozone (O_3)
- Isoprene (C_5H_8)

SPECIES GRAPHS (NO_x)

NO_x Concentrations at Varying NO_x Emission Levels

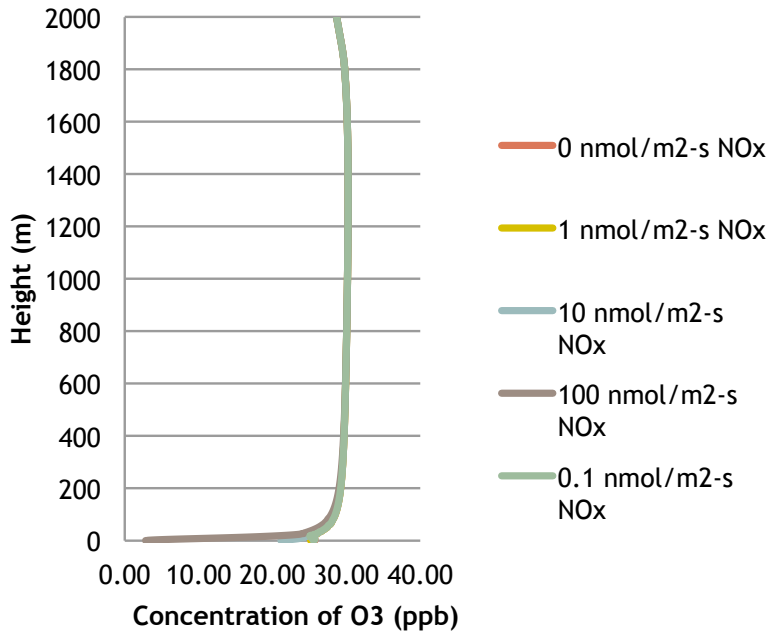

NO_x Concentrations at Varying NO_x Emission Levels

SPECIES GRAPHS (OZONE (O₃))

Ozone Concentration at Varying NO_x Emission Levels

Ozone Concentration at Varying NO_x Emission Levels

SPECIES (ISOPRENE (C₅H₈))

C5H8 Concentration at Varying NOx Emission Levels

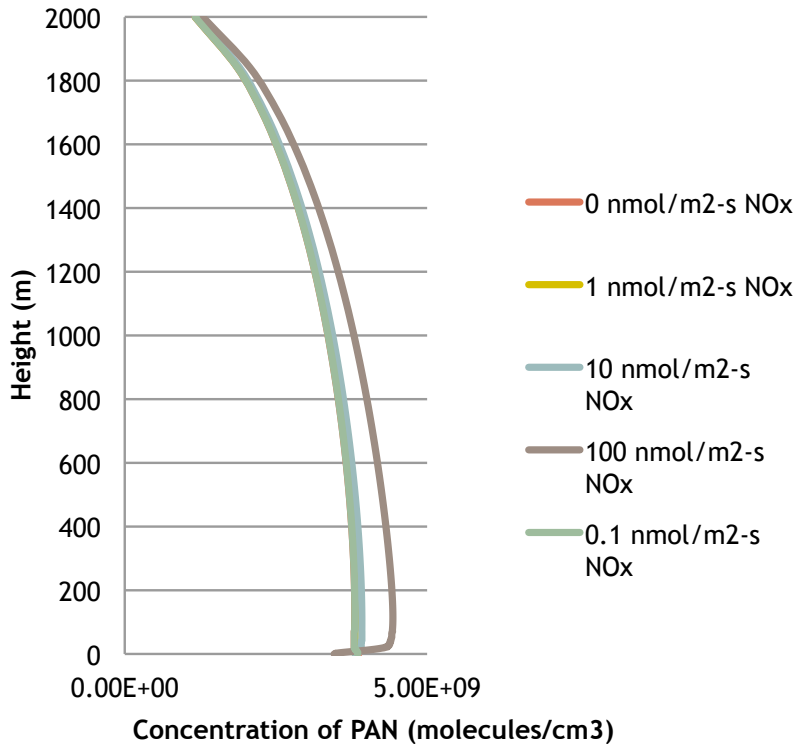

C5H8 Concentration at Varying NOx Emission Levels

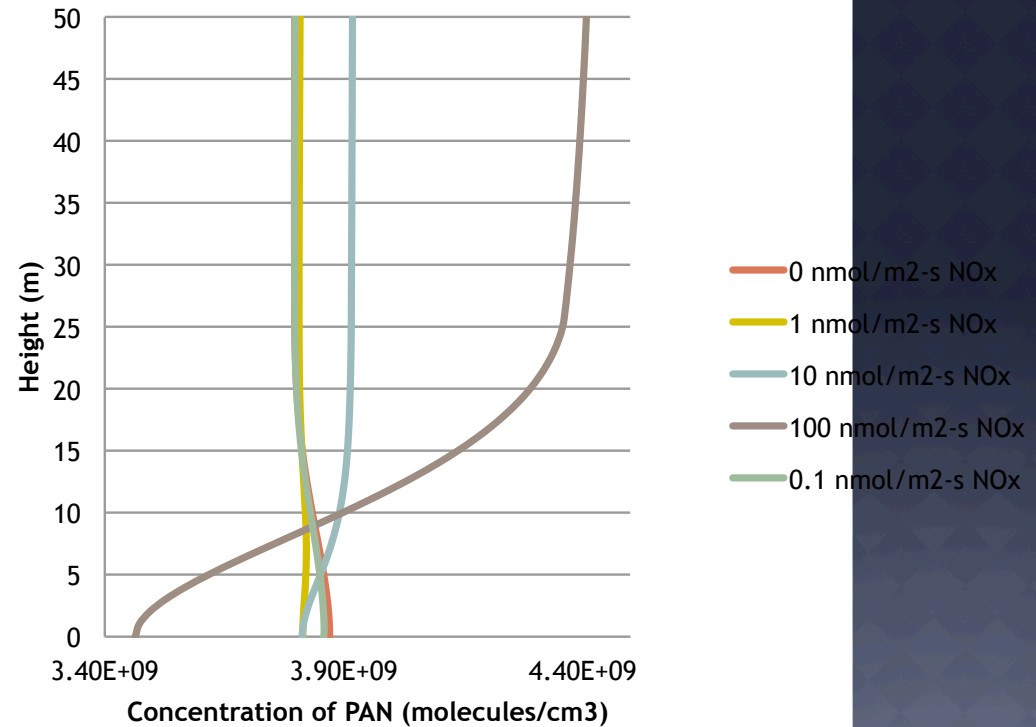

SPECIES (PEROXYACETYL NITRATE (PAN))

PAN Concentration at Varying NOx Emission Levels

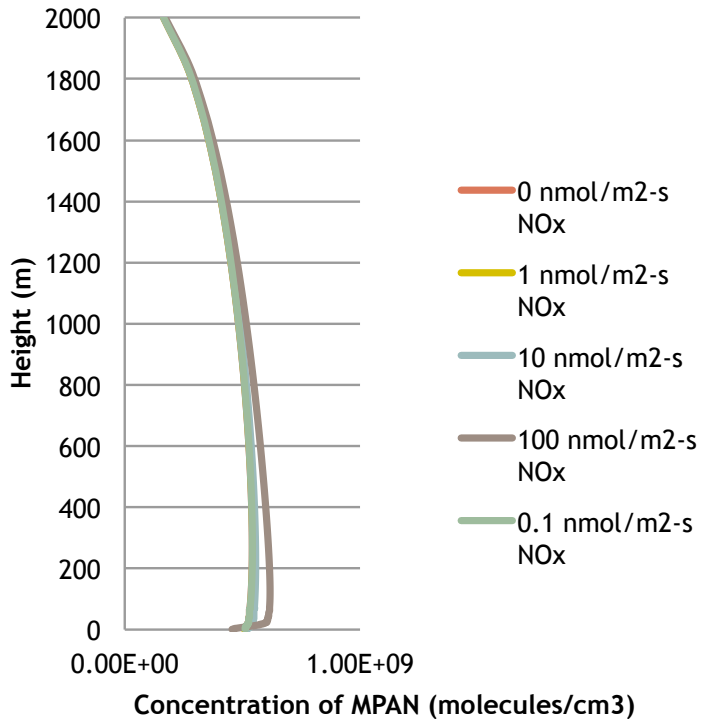

PAN Concentration at Varying NOx Emission Levels

SPECIES (METHACRYLOYL PEROXY NITRATE (MPAN))

MPAN Concentration at Varying NOx Emission Levels

MPAN Concentration at Varying NOx Emission Levels

A lush forest scene with moss-covered rocks and a dirt path. The forest is dense with tall, thin trees, and the ground is covered in vibrant green moss. A dirt path winds through the forest, leading towards the background. The overall atmosphere is serene and natural.

CHEMICAL PRODUCTION GRAPHS

CHEMICAL PRODUCTION (OZONE)

Ozone Budget at Varying NOx Emission Levels

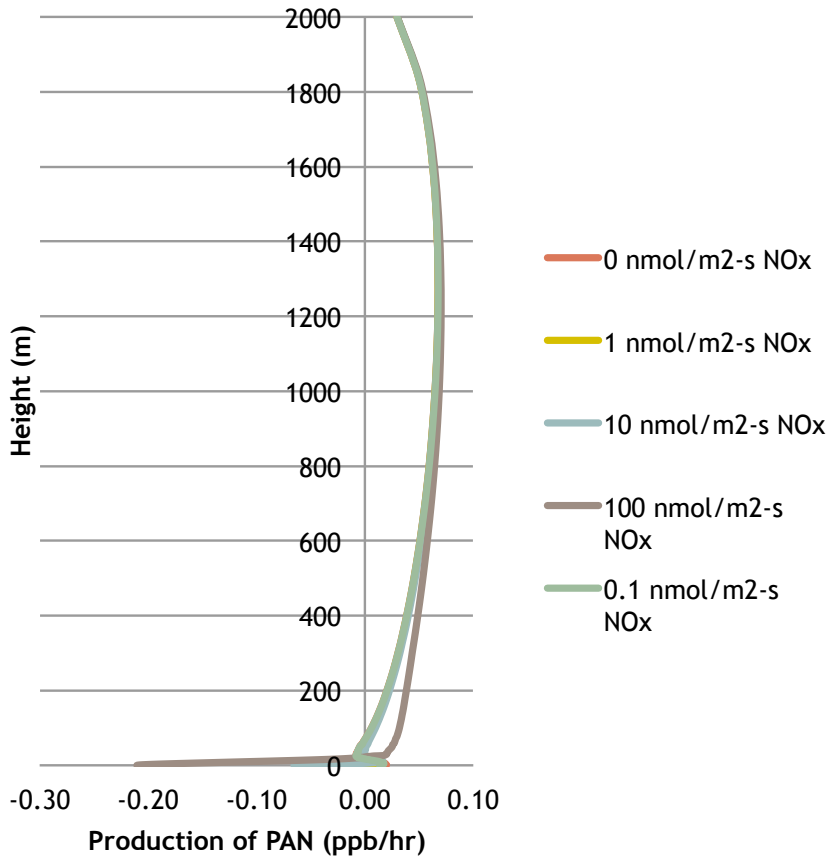

Ozone Budget at Varying NOx Emission Levels

CHEMICAL PRODUCTION (PAN)

PAN Budget at Varying NOx Emission Levels

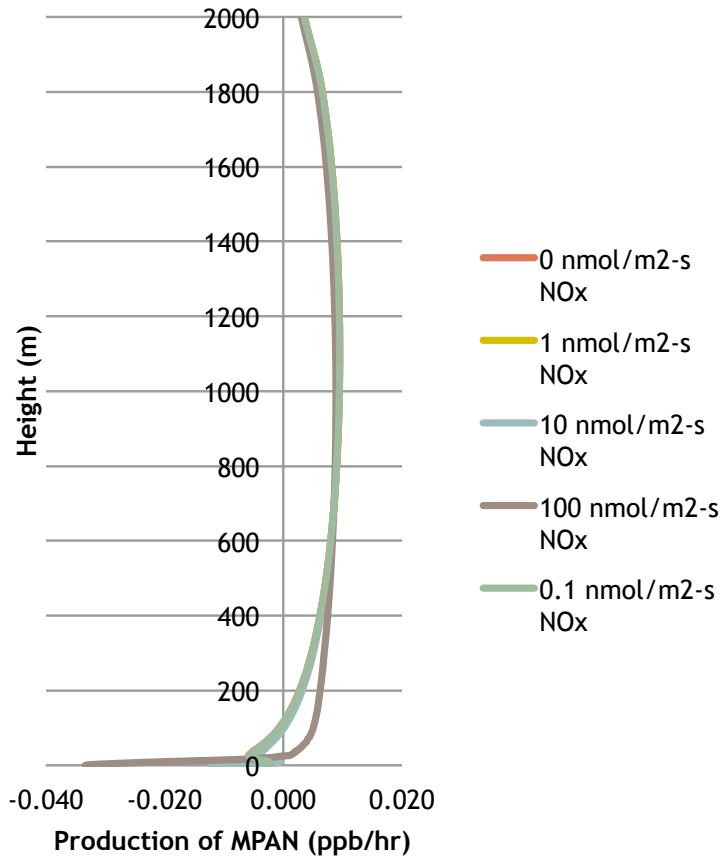

PAN Budget at Varying NOx Emission Levels

CHEMICAL PRODUCTION (MPAN)

MPAN Budget at Varying NOx Emission Levels

MPAN Budget at Varying NOx Emission Levels

A photograph of a dense forest with a dirt path winding through it. The ground is covered in vibrant green moss, particularly on large, rounded rocks. Tall, thin trees with green foliage surround the path. The lighting is soft, creating a serene atmosphere.

VERTICAL FLUX GRAPHS

VERTICAL FLUX (OZONE)

Ozone Vertical Flux at Varying NOx Emission Levels

VERTICAL FLUX (PAN)

PAN Vertical Flux Data at Varying NO_x Emission Levels

PAN Vertical Flux Data at Varying NO_x Emission Levels

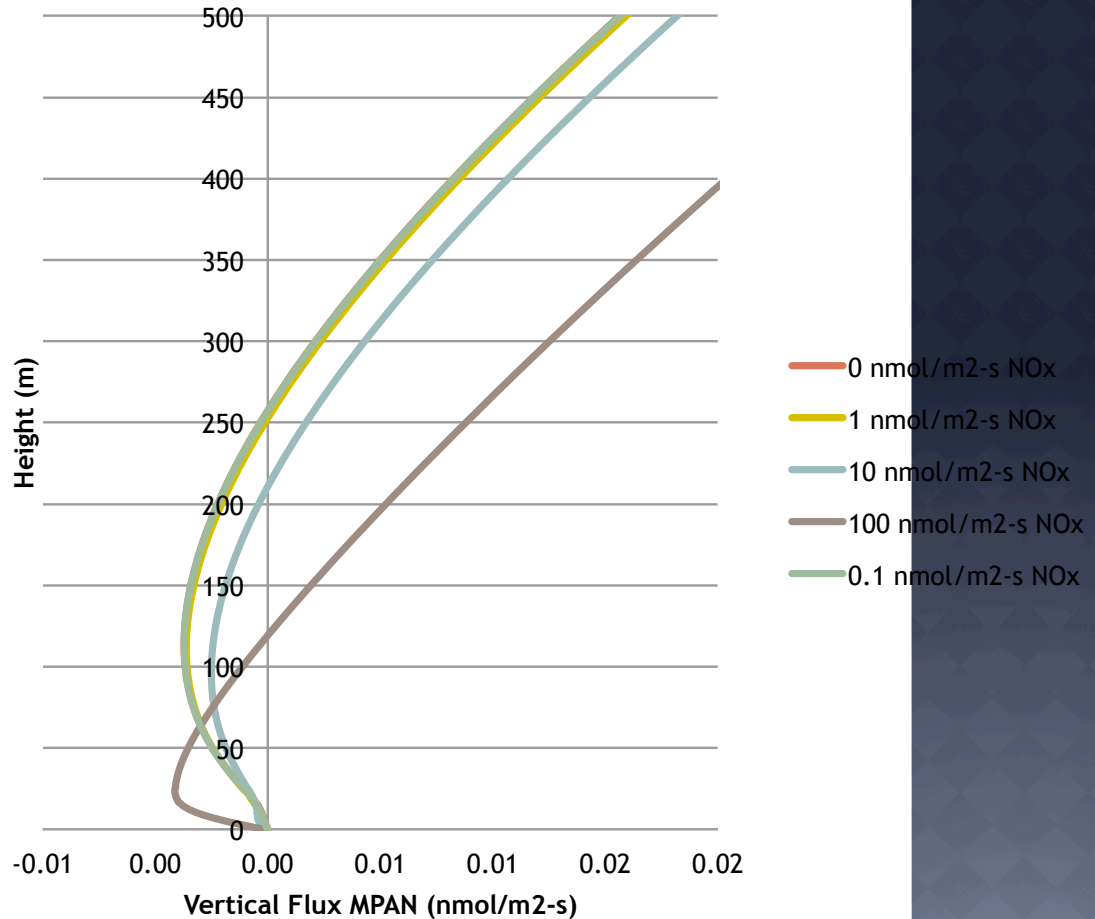

VERTICAL FLUX (MPAN)

MPAN Vertical Flux at Varying NOx Emission Levels

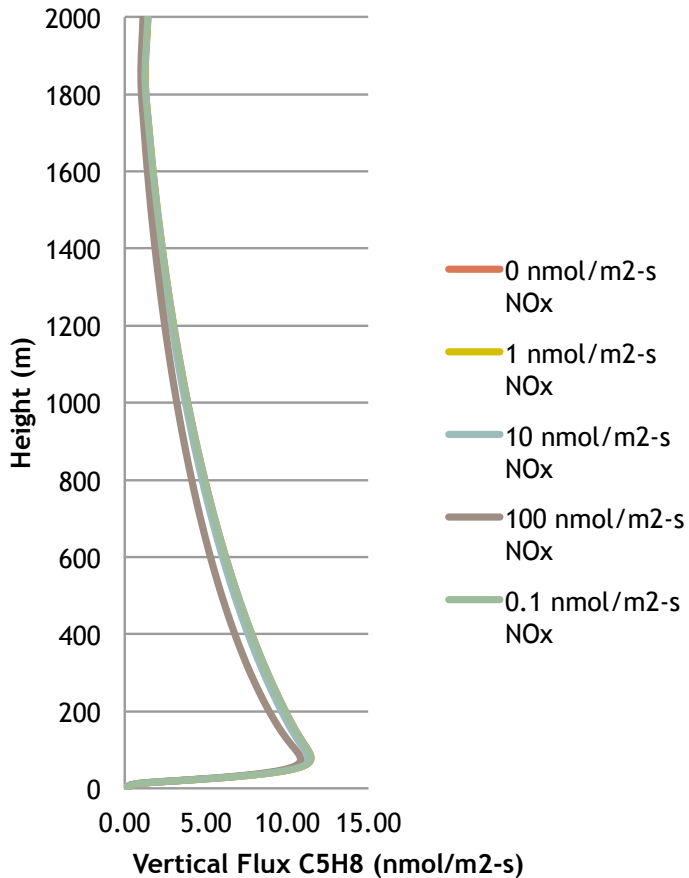

MPAN Vertical Flux at Varying NOx Emission Levels

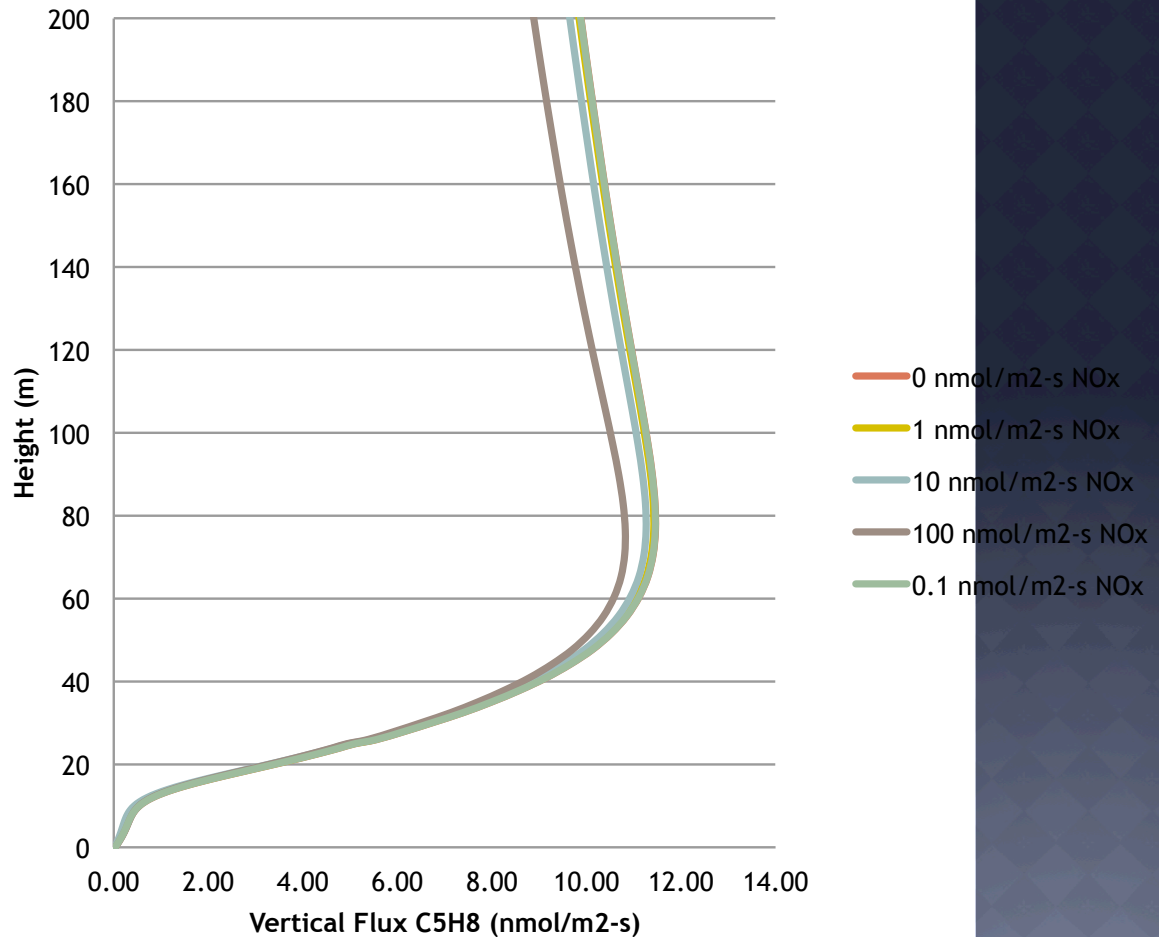

VERTICAL FLUX (ISOPRENE)

C5H8 Vertical Flux at Varying NOx Emission Levels

C5H8 Vertical Flux at Varying NOx Emission Levels

A photograph of a lush forest. The ground is covered in vibrant green moss, particularly on large, rounded rocks. A narrow dirt path winds through the trees, leading towards the background. The trees are tall and thin, with some evergreens and some bare deciduous trees. The lighting is soft, suggesting a misty or overcast day.

FINAL THOUGHTS AND CONCLUSIONS

THOUGHTS ON WHAT THE GRAPHS SAY ABOUT OZONE

- ◉ With increasing traffic within the canopy the direct effect is a reduction of ozone concentrations within the canopy because of the direct reaction with NO and ozone.
 - REACTION: $\text{NO} + \text{O}_3 \rightarrow \text{NO}_2 + \text{O}_2$
- ◉ We are only seeing minor enhancements in ozone concentration above the canopy.

CONCLUSIONS

- Even though we are not seeing direct increases in ozone from NO_x emissions, we are seeing enhanced production of PAN and MPAN above the canopy, which, when transported downwind, can contribute to enhanced ozone formation in areas with little or no NO_x emissions.

PHOTOCHEMICAL CONVERSION OF PAN (OR MPAN) BACK TO NO_x

$T \approx 220 - 273 \text{ K}$

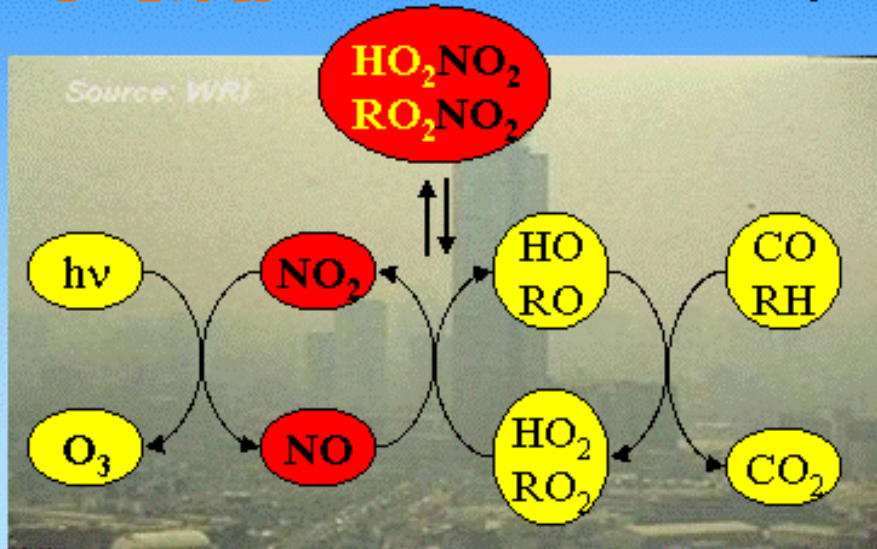

Free Troposphere (2 - 7 km)

$\tau_{\text{APNs}} \sim \text{days} - \text{months}$

$T > 273 \text{ K}$

Boundary Layer (0 - 2 km)

$\tau_{\text{APNs}} \sim \text{mins} - \text{hrs}$

- URL: <http://www.atmos.washington.edu/~thornton/PANs.html>

CONCLUSIONS (CONT.)

- Under the environmental conditions studied so far in our simulations, only minor amounts of local ozone production above the canopy are predicted. However, the simulation results suggest that the enhancements in PAN and MPAN formation from visitor traffic in the park may lead to increased ozone concentrations downwind from major highways within the park. Ozone data within and downwind of the park will be further analyzed to test the model prediction.
- Results and further analysis of this work will be published in a journal article at a later date.
